

Breakpoint

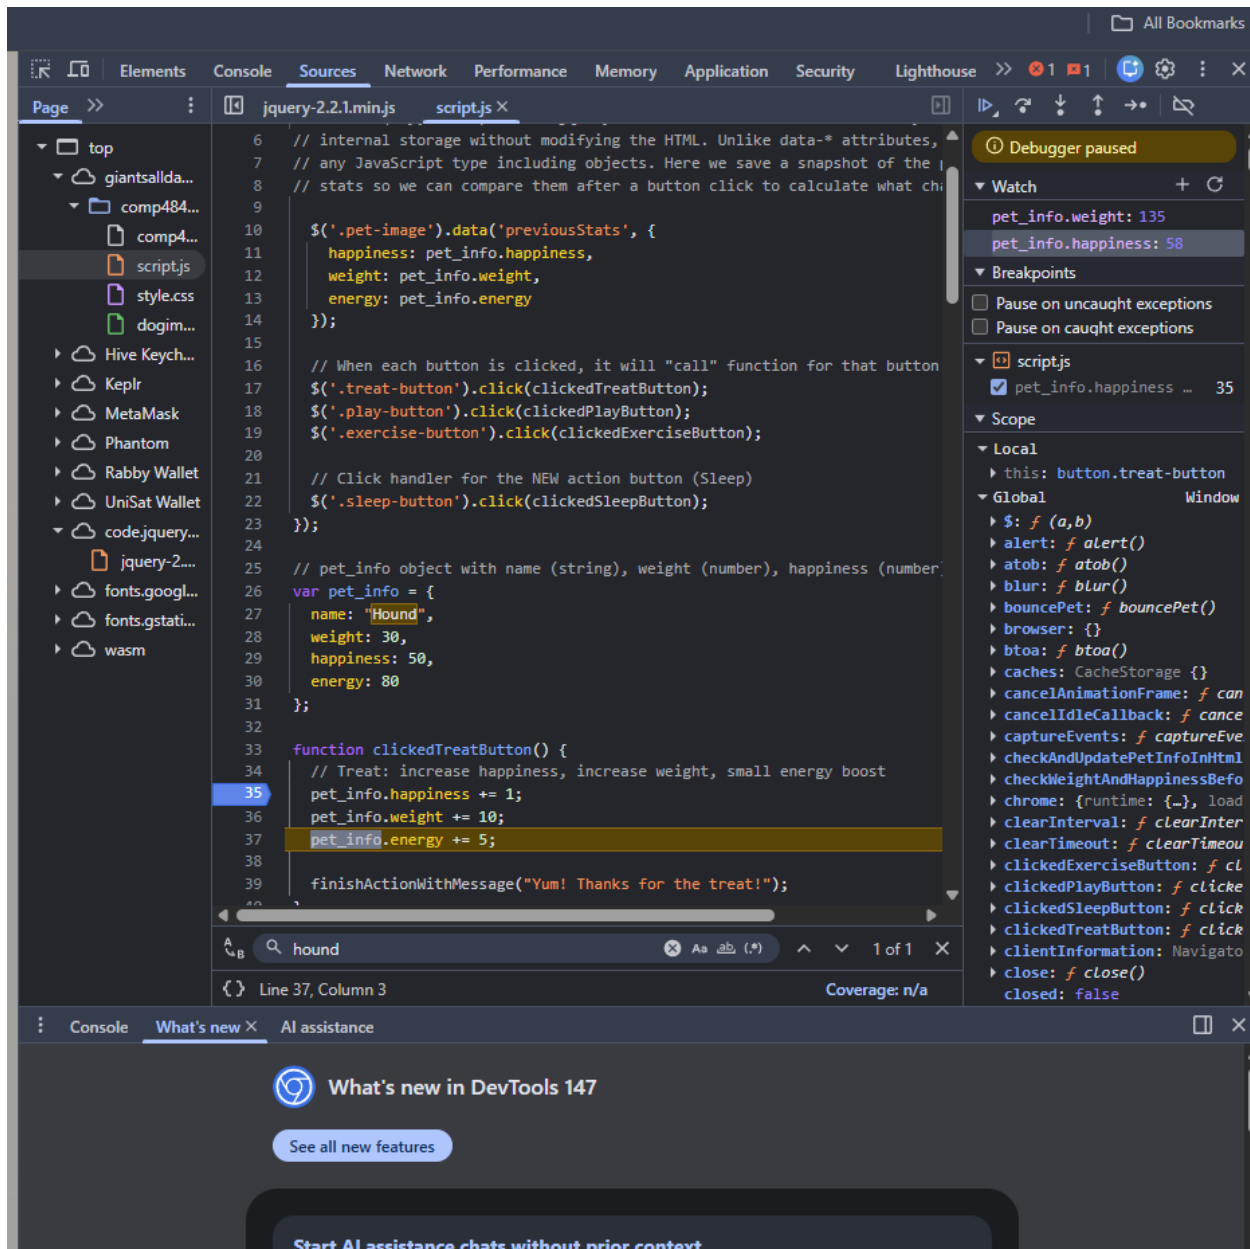

Practical examples I would use is the breakpoint. I think this is a very vital tool and use case for figuring out and debugging why certain numbers don't seem to add up when they are supposed and to see how each click of a button changes the values more so than just what is "supposed" to happen. Whether there is an extra + or - that you figure out has been messing up the numbers the breakpoint can help you identify where exactly all numbers are adding up from up to that point.

The Scope Panel

This shows specifically where the data is being updated after the breakpoint and on the right panel it is showing the numbers and variables being updated as you pass through.

Watch

This watch allows me to add variables and watch them as we step through the code without having to go all the way down to the pet_info every time.
